### **Homework 1: Face Detection**

## 110550108 施柏江

## Part I. Implementation (6%):

#### ↓ Part 1

```
# Begin your code (Part 1)
        # raise NotImplementedError("To be implemented")
        1. Create a list 'dataset' to store the data of all images
        2. Use 'os.path.join()' to get the path of face and non-face folders
        3. Use 'os.listdir()' to get all files in the folder
        4. Use 'cv2.imread()' to read the image and
            use 'cv2.IMREAD_GRAYSCALE' to convert to greyscale
        5. If current path is 'face', the second element will be 1.
            Otherwise, 0.
        6. Finally, add the tuple to the 'dataset'
        dataset = []
        path = os.path.join(dataPath, 'face')
        files = os.listdir(path)
         for file in files:
          img = cv2.imread(os.path.join(path, file), cv2.IMREAD_GRAYSCALE)
          dataset.append((img, 1))
        path = os.path.join(dataPath, 'non-face')
        files = os.listdir(path)
         for file in files:
          img = cv2.imread(os.path.join(path, file), cv2.IMREAD_GRAYSCALE)
          dataset.append((img, 0))
37
```

### ↓ Part 2

```
# Begin your code (Part 2)
2. The first loop iterates through every weak classifier
3. The second loop iterates through every integral image
4. If featureVals[i][j] < 0, it means that the classifier identifies the image
5. If the image is identified wrongly, add its weight to 'error'
6. Return the weak classifier with minimum error
bestError = float('inf')
bestIndex = -1
for i in range(len(features)):
    error = 0
    for j in range(len(iis)):
        isFace = (featureVals[i][j] < 0)</pre>
       error += weights[j] * (abs(isFace - labels[j]))
    if error < bestError:</pre>
       bestIndex = i
        bestError = error
bestClf = WeakClassifier(features[bestIndex])
return bestClf, bestError
# End your code (Part 2)
```

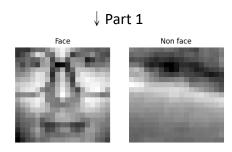

```
# Begin your code (Part 4)
17
         # raise NotImplementedError("To be implemented")
         1. Create 'locations' to store the location and size of each face,
             'filenames' to store the name of each image,
             and 'line_cnt' to store the number of faces of each image
         Use 'open()' to open 'detectData.txt'
22
         3. Use 'readlines()' to read in the information line by line
         Use 'strip()' to remove any leading and trailing spaces
         5. Use 'split()' to split the line into a list
         6. If the first item in the list is a number,
             it means that this line is the information about location.
            Otherwise, it is about filename.
         7. Use 'os.path.join()' to get the path of the image
         8. Use 'cv2.imread()' to read the image
         9. Because the image has to be grey when classifying,
            use 'cv2.IMREAD_GRAYSCALE' to convert it to greyscale
         10. Because we have to draw green and red rectangles in the final result,
            create 'img ori' to store the original image
         11. Create 'crop img' to store the cropped image,
             and then resize it to (19, 19)
         12. After trying all of the interpolation methods,
             'cv2.INTER_NEAREST' perform the best, so I choose it.
         13. If the cropped image is identified as a face, draw a green rectangle on it.
             Otherwise, draw a red one.
```

```
43
         GREEN = [0, 255, 0]
44
         RED = [0, 0, 255]
45
         locations = []
47
         filenames = []
48
         line_cnt = []
49
         with open(dataPath, 'r') as f:
50
           i = 0
51
           for line in f.readlines():
52
53
             line = line.strip()
54
              strs = line.split(' ')
              if str.isdigit(strs[0]):
55
56
                locations.append([])
57
                for j in range(4):
                  locations[i].append(int(strs[j]))
58
59
                i += 1
60
              else:
61
                filenames.append(strs[0])
62
                line cnt.append(int(strs[1]))
```

```
file_cnt = 0
         line idx = 0
         for line in line_cnt:
           path = os.path.join('data/detect', filenames[file_cnt])
67
           file cnt += 1
           img = cv2.imread(path, cv2.IMREAD_GRAYSCALE)
70
           img_ori = cv2.imread(path)
           for _ in range(line):
71
             x = locations[line_idx][0]
             y = locations[line idx][1]
             w = locations[line_idx][2]
             h = locations[line_idx][3]
75
76
             crop_img = img[y:y+h, x:x+w]
             crop_img = cv2.resize(crop_img, (19, 19), interpolation=cv2.INTER_NEAREST)
             ans = clf.classify(crop_img)
79
             if ans:
               cv2.rectangle(img_ori, (x, y), (x+w, y+h), GREEN, 2)
81
             else:
               cv2.rectangle(img_ori, (x, y), (x+w, y+h), RED, 2)
82
             line idx += 1
           cv2.imshow('result', img_ori)
           cv2.waitKey(0)
           cv2.destroyAllWindows()
87
         # End your code (Part 4)
```

## Part II. Results & Analysis (12%):

### 1. Results:

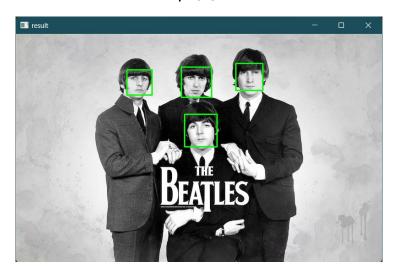

↓ Part 2

```
Run No. of Iteration: 9
Chose classifier: Weak Clf (threshold=0, polarity=1, Haar feature (positive regions=[RectangleRegion(10, 4, 1, 1)], negative regions=[RectangleRegion(9, 4, 1, 1)]) with accuracy: 152.000000 and alpha: 0.707795
Run No. of Iteration: 10
Chose classifier: Weak Clf (threshold=0, polarity=1, Haar feature (positive regions=[RectangleRegion(4, 9, 2, 2), RectangleRegion(2, 11, 2, 2)], negative regions=[RectangleRegion(2, 9, 2, 2), RectangleRegion(4, 11, 2, 2)]) with accuracy: 137.000000 a nd alpha: 0.811201

Evaluate your classifier with training dataset
False Positive Rate: 17/100 (0.170000)
False Negative Rate: 0/100 (0.000000)

Evaluate your classifier with test dataset
False Positive Rate: 45/100 (0.450000)
False Negative Rate: 36/100 (0.360000)
Accuracy: 119/200 (0.595000)
```

# $\downarrow \text{ Part 4}$

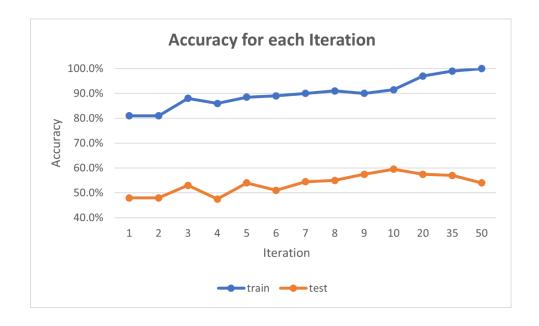

↓ Part 5

## 2. Analysis:

↓ Part 3

200張	train data accuracy	test data accuracy
method 1 $t=1$	81.0%	48.0%
method 1 t=2	81.0%	48.0%
method 1 t=3	88.0%	53 <b>.0%</b>
method 1 t=4	86.0%	47.5%
method 1 t=5	88.5%	54.0%
method 1 t=6	89.0%	51. <b>0%</b>
method 1 t=7	90.0%	<b>54.5%</b>
method 1 t=8	91.0%	55 <b>.0%</b>
method 1 t=9	90.0%	57.5%
method 1 $t=10$	91.5%	59.5 <b>%</b>
method 1 t=20	97.0%	57.5 <b>%</b>
method 1 $t=35$	99.0%	57. <b>0%</b>
method 1 t=50	100.0%	<b>54.0%</b>

As t increases, train data accuracy gradually increases. When t=50, it even reaches 100%. This is because the model learned based on the train data, so if the train data is trained multiple times, train data accuracy obtained will be higher and higher. However, for test data accuracy, it initially increases as t increases, but after t=10, it starts to drop. This is due to overfitting. When the model is trained too many times on the same train data, it loses the ability to distinguish generalized datasets to fit outliers.

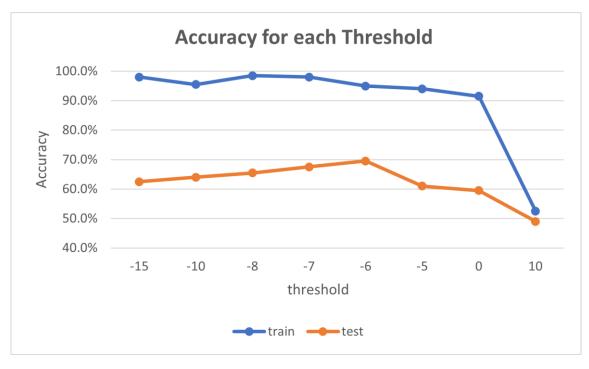

#### 3. Bonus:

```
↓ Part 6
```

```
177
                       # Begin your code (Part 6)
178
                       bestError = float('inf')
179
                       bestIndex = -1
180
                       for i in range(len(features)):
                           error = 0
181
                           for j in range(len(iis)):
182
183
                               isFace = (featureVals[i][j] < 0)</pre>
184
                               error += weights[j] * (abs(isFace - labels[j]))
                           if error < bestError:</pre>
                               bestIndex = i
187
                               bestError = error
                       bestClf = WeakClassifier(features[bestIndex], threshold=-6)
                       # End your code (Part 6)
190
                       return bestClf, bestError
```

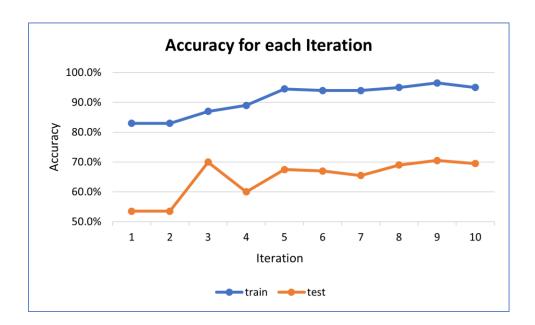

Unlike in part 2, I changed the value of the threshold. I tested values ranging from -15 to 10 and found that the test data accuracy was highest at around 70% when the threshold was set to -6.

threshold(T=10)	train data accuracy	test data accuracy
-15	98.0%	62.5 <b>%</b>
-10	95.5 <b>%</b>	64.0%
-8	98.5%	65.5 <b>%</b>
-7	98.0%	67.5 <b>%</b>
-6	95.0%	69.5 <b>%</b>
-5	94.0%	61.0%
0	91.5%	59.5 <b>%</b>
10	52.5 <b>%</b>	49.0%

Therefore, I decided to test the accuracy of T values ranging from 1 to 10 using the threshold of -6.

200張	train data accuracy	test data accuracy
method $2 t=1$	83.0%	53 <b>.</b> 5%
method 2 t=2	83.0%	53 <b>.</b> 5%
method $2 t=3$	87.0%	70.0%
method 2 t=4	89.0%	60.0%
method $2 t=5$	94.5%	67.5%
method 2 t=6	94.0%	67.0%
method 2 t=7	94.0%	65.5 <b>%</b>
method 2 t=8	95 <b>.0%</b>	69.0%
method 2 t=9	96.5%	70.5%
method 2 $t=10$	95 <b>.0%</b>	69.5%

Compared to parts 2 and 3, not only did the train data accuracy increase in part 6, but the test data accuracy also reached around 70%, which is an increase of about 10%. This indicates that the approach taken in part 6 has better classification ability for generalized datasets.

## Part III. Answer the questions (12%):

1. Please describe a problem you encountered and how you solved it.

Ans: A problem I faced while completing this assignment was my unfamiliarity with image processing using Python. The assignment involved numerous image operations, including reading, cropping, resizing, among others. As a result, I spent an amount of time searching for relevant documentation on these operations, and I finally figured it out.

- 2. What are the limitations of the Viola-Jones' algorithm?
- Ans: 1. Limited accuracy. The algorithm relies on a fixed set of features to detect faces, so it is not sufficient to accurately detect all kinds of faces.
  - 2. Limited detection range. The algorithm is designed to work best on frontal faces.
  - 3. Long processing time. The algorithm can be computationally intensive.
- 3. Based on Viola-Jones' algorithm, how to improve the accuracy except changing the training dataset and parameter T?

Ans: Increasing the scale of the image can help to improve the accuracy because larger images provide more detail.

- 4. Other than Viola-Jones' algorithm, please propose another possible face detection method (no matter how good or bad, please come up with an idea). Please discuss the pros and cons of the idea you proposed, compared to the Adaboost algorithm.
- Ans: A possible algorithm to detect faces involves first identifying the eyes, and then using their relative positions to locate the ears, nose, and mouth. If these facial features are all detected in the correct positions, then the algorithm can conclude that a face is present in the image. One advantage of this approach is that it may be faster than the Adaboost algorithm. However, a limitation of this method is that it is more restricted to detecting faces that are directly facing the camera and the accuracy may be lower than the Adaboost algorithm.
